

# AutoResponse

From Alert Triage to Containment and Reporting

# Objective + Vision

- Use LLM models to reason on threat severities and containment decisions
- Improve consistency in triage and containment decisions.
- Combine threat intelligence, correlation, and reporting into one automated workflow.
- Move toward a practical, real-world cyber defense assistant.

# Why Multi-Agent AI?

- Different agents specialize in different tasks (triage, correlation, threat intel, containment, reporting).
- Agents collaborate through an orchestrator, simulating a real SOC team workflow.
- Modular design allows components to be improved independently.
- Demonstrates how AI agents can coordinate decisions, not just perform isolated tasks.

# Demo

- A simulated security alert is generated.
- Agents analyze logs and threat context.
- The system makes a containment decision.
- Containment is executed in a mock environment.
- A final incident report is generated automatically.

# What's Next?

- Deploy the project on a vulnerable Docker image to capture real attack logs.
- Test with either external traffic sources or manual penetration attempts.
- Replace the mock containment module with real configuration changes on an actual network or host system.
- Validate safety, rollback, and reliability in a realistic environment.
